

¹ It similarly is said that there is no increase in market concentration, unlike a horizontal merger.² In this comment, we question both of these claims. We show that there is an inherent loss of an *indirect competitor* and competition when there is an input foreclosure concern. We also show that it is possible to calculate an *effective increase* in the HHI measure of concentration for the downstream market, when the competitive concern is input foreclosure. We refer to this “proxy” measure as the “*dHHI*.” The *dHHI* (and associated *post-merger HHI*) can be used as potentially probative evidence in vertical merger matters. In principle, these concentration measures also might be useful in the formation of safe harbors or anticompetitive presumptions for input foreclosure concerns, perhaps in conjunction with other evidence. The draft Vertical Merger Guidelines (“VMGs”) suggest a safe harbor based on shares, not concentration.³

We derive the *dHHI* measure by comparing the pricing incentives and associated upward pricing pressure (“UPP”) involved in two alternative types of acquisitions: (i) vertical mergers that raise

PUBLIC COMMENT 3 (January 10, 2020) [hereinafter *draft VMGs*], https://www.ftc.gov/system/files/documents/public_statements/1561715/p810034verticalmergerguidelinesdraft.pdf.

unilateral input foreclosure concerns (and the associated vertical GUPPI measures),⁴ and (ii) horizontal acquisitions of partial ownership interests among competitors that raise unilateral effects concerns (and the associated modified GUPPI and modified HHI measures).⁵

This connection between the vertical GUPPIs (“vGUPPIs”) for vertical mergers and the modified HHIs (“mHHIs”) for horizontal partial ownership transactions demonstrates the horizontal nature of the concern raised by potential input foreclosure in vertical mergers and how this horizontal concern is connected to the unilateral effects concern from horizontal mergers or horizontal partial ownership transactions. The connection demonstrates that there is not an “inherent” difference in the competitive concerns, as is sometimes claimed. The impact on pricing incentives and effective concentration from input foreclosure concerns is the same as the impact of an identifiable hypothetical horizontal consolidation involving partial ownership interests between the downstream merging firm and its potentially foreclosed rivals.

The *dHHI* is based on the way in which the pricing incentives that arise in vertical mergers involving unilateral input foreclosure concerns are similar to the pricing incentives arising from partial ownership interests among competing firms. It is derived analytically from consideration of two UPP measures—the vGUPPIs used to gauge unilateral input foreclosure effects and the modified GUPPIs (“mGUPPIs”) that are used to gauge unilateral price effects from partial ownership interests among horizontal competitors—and the associated *mHHI* concentration measure. While our main focus here is the proxy *dHHI* measure, we also explain for completeness how a safe harbor or anticompetitive presumption might be based directly on the vGUPPIs themselves, and briefly discuss criticisms of the use of vGUPPIs for scoring the effects of vertical mergers on pricing incentives.

We frame our basic formal analysis of input foreclosure in the context of a standard vertical industry model in which the upstream firms are Bertrand competitors selling differentiated inputs to downstream firms, and the downstream firms are Bertrand competitors selling differentiated substitute products to consumers.⁶ The vertically merged firm may have the incentive to engage

⁴ Serge Moresi & Steven. C. Salop, *vGUPPI: Scoring Unilateral Pricing Incentives in Vertical Mergers*, 79 ANTITRUST L.J. 185 (2013).

⁵ U.S. DEP’T OF JUSTICE & FED. TRADE COMM’N HORIZONTAL MERGER GUIDELINES 33

in an input foreclosure strategy by raising the price of the input charged to one or several targeted downstream rivals. In extreme cases, the merged firm may have the incentive to raise the input price to a prohibitively high level that totally forecloses the (targeted) downstream rivals from access to its input. Such partial or total input foreclosure can be profitable to the merged firm because it can raise the costs faced by the downstream rivals, and hence can lead to diversion of sales from the downstream rivals to the downstream merging firm. It simultaneously can lead the downstream rivals to raise prices to consumers, which then can allow the downstream merging firm to increase its price, its market share or some combination of the two.⁷

At the outset, we want to emphasize several features of the *dHHI* and *vGUPPI* measures as well as some associated caveats and limitations.

First, we recognize that the *dHHI* measure is limited only to the downstream market, so it may need to be combined with the level of concentration for the upstream market (or the supply of the input by the upstream merging firm to firms in the downstream market⁸). Its accuracy also is subject to limitations, just as are concentration measures used for horizontal mergers. However, the *dHHI* has some intuitive properties that can make it a useful addition to the antitrust toolkit.

Second, our formal model focuses on the effects of a vertical merger on unilateral incentives to engage in input foreclosure, and examines only “first round” effects. Input foreclosure conduct likely also would lead to pricing effects by rival firms at either level of the vertical supply chain. Total foreclosure or price increases by the upstream merging firm may lead its competitors to

account that raising the price of its input to a given downstream firm will induce that downstream firm to increase its downstream price in response. See Roman Inderst & Tommaso Valletti, *Incentives for Input Foreclosure*, 55 EUR. ECON. REV. 820 (2011); Moresi & Salop, *supra* note 4. Other models assume that each upstream firm negotiates bilaterally with each downstream firm over the price of the input. See, e.g., Patrick Rey & Thibaud Vergé, *Secret Contracting in Multilateral Relations* (Nov. 26, 2019), <https://www.tse-fr.eu/sites/default/files/TSE/documents/doc/by/rey/secret.pdf>; Serge Moresi, *Vertical Mergers and Bargaining Models: Simultaneous versus Sequential Pricing* (Feb. 19, 2020), https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3541099.

⁷ The input foreclosure also could lead to accommodating responses either by the upstream rivals of the merged firm (they also would increase their input prices to the targeted downstream rivals) or by the non-targeted downstream rivals (they also would increase their output prices to consumers). These accommodating responses would exacerbate the anticompetitive effects of input foreclosure. Thomas G. Krattenmaker & Steven C. Salop, *Anticompetitive Exclusion: Raising Rivals' Costs to Achieve Power over Price*, 96 YALE L.J. 209 (1986); Janusz A. Ordover, Garth Saloner & Steven C. Salop, *Equilibrium Vertical Foreclosure*, 80 AM. ECON. REV. 127 (1990).

⁸ See draft VMGs, *supra* note 3, at 2 (“Example 1: A retail chain buys a manufacturer of cleaning products. In this example, the Agencies may identify two relevant markets. The first potential relevant market is the supply of cleaning products to retail customers in a given geographic area. For this relevant market, the related product is the supply of the cleaning products by the manufacturer to retailers in the geographic area.”).

respond with accommodating price increases of their own. These price increases might be unilateral (or more strictly, multilateral) or they may be coordinated.⁹ At the downstream level, input foreclosure may raise the costs of a maverick competitor, which could facilitate coordination at that level.¹⁰ While coordination can play a role in input foreclosure, we are not explicitly taking account of coordinated effects theories of harm in the formal model. The *dHHI* (like the vGUPPIs) does not take any of these possibilities into account. However, we will discuss the role of coordinated conduct outside the formal model.

Third, we are focusing on input foreclosure, not customer foreclosure. While the analysis of customer foreclosure is analogous, it also differs in some ways. It typically involves reducing rivals' revenues instead or in addition to increasing rivals' costs. The *dHHI* (like the vGUPPIs) is *not* derived here with an eye towards customer foreclosure.¹¹

Fourth, because we are focusing on concentration (and its possible use as a safe harbor screen or anticompetitive presumption), we will not take into account any merger-specific elimination of double marginalization ("EDM") or other cognizable efficiencies. This is the same approach taken for horizontal mergers. Of course, any cognizable efficiencies would be analyzed if the merger is investigated further.

The remainder of this comment is organized as follows. In Section II, we show how the vertically merging firms are "indirect competitors" in the pre-merger world and how the merger is like a horizontal consolidation that eliminates this indirect competition. In Section III, we derive the *dHHI* to proxy for the increase in effective concentration in the downstream market and explain how it can be measured in practice. The *dHHI* is based on vGUPPIs, the relationship between vertical and horizontal GUPPIs, and the *mHHI* for horizontal acquisitions of partial ownership interests. In Section IV, we discuss how the *dHHI* can be used in practice to form a general indicator (like the *delta HHI* in horizontal mergers), a safe harbor, or an

⁹ We assume unilateral conduct pre-merger. Intuitively, if pre-merger the upstream merging firm were to raise its input prices to downstream firms, the other upstream firms would not match the price increase because they would anticipate that the upstream merging firm likely would then "cheat" and reduce price. So, upstream coordination does not occur pre-merger. Post-merger, however, upstream coordination targeted at the rivals of the downstream merging firm is more likely to occur than pre-merger. The reason is that the upstream merging firm would have a weaker incentive to "cheat" since reducing its input prices to downstream rivals would reduce the downstream profit earned by the downstream merging firm.

¹⁰ Downstream coordination increases the profit of the downstream merging firm, but reduces the profit that the upstream merging firm earns from sales to downstream rivals. It is possible that the overall effect of downstream coordination would be to increase the total profits of the merged firm.

¹¹ It is the case that customer foreclosure can lead to input foreclosure. For example, suppose customer foreclosure leads a targeted upstream rival or rivals to lose substantial sales and this raises their marginal costs or leads to exit. As a result, the upstream merging firm (and its remaining competitors) may gain the power to raise input prices to the rivals of the downstream firm, either unilaterally or through coordinated action. This input foreclosure then could raise the costs of the downstream rivals and harm consumers. However,

anticompetitive presumption. In Section V, we briefly explain that the vGUPPIs themselves could be used instead of the *dHHI*, address some criticisms that have been made of the vGUPPI methodology in two recent working papers, and derive *simultaneous* vGUPPIs in response. Section VI concludes.

II. Are the Potential Competitive Effects of Vertical Mergers Inherently Different from Horizontal Mergers?

While there is no increase in the nominal level of concentration in the downstream market from a vertical merger, our analysis shows that there is a loss of an indirect competitor and therefore an increase in effective concentration in the downstream market. We also show how to derive a proxy *dHHI* measure for the increase in effective concentration. These two ideas of indirect competition and effective concentration flow from the same economic analysis.

We derive the *dHHI* measure by comparing the vGUPPIs for vertical mergers that raise unilateral input foreclosure concerns and the mGUPPIs for horizontal acquisitions of partial ownership interests among competitors that raise unilateral effects concerns. Specifically, we show that the effects on pricing incentives from a vertical merger are identical to the effects on pricing incentives from a particular hypothetical transaction involving partial ownership interests among the downstream firms (in the sense that the mGUPPIs would be equal to the vGUPPIs). We then define the *dHHI* as equal to the increase in the *mHHI* from the equivalent hypothetical horizontal transactions.

These connections between the vGUPPIs and the mHHIs for partial ownership transactions demonstrate the horizontal nature of the concern raised by input foreclosure in vertical mergers and how this horizontal concern can be related to the unilateral effects concern from horizontal mergers or horizontal partial ownership transactions. The connections also demonstrate that the underlying economic analysis does not involve an “inherent” difference in competitive concerns. This latter property is derived in the formal model to follow.

To understand at an intuitive level the relationship between the competitive concerns of the two types of mergers, a useful starting point is the claim that a vertical merger does not inherently eliminate a competitor or competition, unlike a horizontal merger. While this observation might appear to apply in a superficial sense, economic analysis of input foreclosure shows why it is not economically correct. The error is that the claim ignores the fact that in the pre-merger market, the (future) upstream merging firm is an “indirect competitor” of the (future) downstream merging firm. This is because the upstream firm sells inputs to the competitors of the (future) downstream merger partner, and therefore has a role in “supporting” competition in the downstream market.

inputs from the upstream merging firm.¹⁴ This is another inherent horizontal effect.¹⁵ Intuitively, from the perspective of the downstream merging firm, the upstream merging firm has a “financial interest” in each downstream rival to which it sells inputs; when the rival sells an additional unit to consumers, the upstream merging firm obtains a “dividend” equal to the upstream merging firm’s margin on input sales to that rival. Through the vertical merger, therefore, the downstream merging firm acquires a “financial interest” in each rival supplied by the upstream merging firm. To illustrate, suppose that a rival of the downstream merging firm purchases one unit of input from the upstream merging firm for each unit of output that it produces. Suppose further that the dollar margins of the rival and the upstream merging firm are equal. Then, the vertical merger would have the same effect on the pricing incentives of the downstream merging firm as a hypothetical horizontal merger between the downstream merging firm and the rival. If the dollar margin of the upstream merging firm is smaller than the dollar margin of the downstream rival, the equivalent hypothetical horizontal transaction would be the acquisition of a partial ownership interest in the rival, and not a full merger. This inherent horizontal ef # # # onf n U in

argin

dHHI is equal to the increase in the *mHHI* from both of these hypothetical horizontal transactions taken together.¹⁶

A. Hypothetical Horizontal Transaction to Capture the UPP of the Targeted Downstream Rivals

The driving force of our analysis is that the merging firms may be indirect competitors in the pre-merger market. If an upstream firm is supplying inputs to the rivals of a downstream firm, that upstream firm is in effect *supporting competition* in the downstream market by the rivals of that downstream firm. It is in this sense that the upstream merging firm is an *indirect competitor* of the downstream merging firm in the pre-merger market.

The vertical merger specifically may reduce or eliminate the incentives of the upstream merging firm to support the competition from the rivals of the downstream merging firm. The vertical merger thus creates a type of *indirect horizontal consolidation* between the downstream merging firm and each foreclosed rival firm. The *dHHI* concept is a way to capture this consolidation with a concentration measure based on the analysis of the incentive effects of partial ownership interests among competitors. More precisely, instead of thinking about a targeted downstream rival as having an incentive to raise its price because the upstream merging firm raised the input price to that rival, we proxy for this effect by determining that rival's *identical incentive* to raise price "as if" it had acquired a silent partial financial interest in the downstream merging firm. This equivalent hypothetical horizontal partial ownership transaction is a useful way to look at the potential effect of the vertical merger on the targeted downstream rival. If there are multiple downstream firms targeted for input foreclosure, then there will be additional such hypothetical horizontal transactions. The incentive effect of these hypothetical horizontal transactions can be gauged as an increase in the *mHHI* of the downstream market.¹⁷ The *dHHI* measure then is defined as the increase in the *mHHI* resulting from these equivalent hypothetical horizontal transactions (and from the other transactions discussed in Section III.B below).

In our vGUPPI article,¹⁸ we gauge the resulting effect on the pricing incentives of the foreclosed rival(s) with the vGUPPIr measure.¹⁹ We next briefly review this measure and then explain how we derive the hypothetical, equivalent horizontal transaction and the corresponding increase in the *mHHI*.

¹⁶ For input foreclosure, the draft VMGs formally define only a downstream market, using the same market definition methodology as in the HMGs. See draft VMGs, *supra* note 3, §2. In addition, the draft VMGs define an upstream "related product." *Id.* at Examples 1 and 2. t

standard horizontal GUPPI of the rival for a hypothetical merger with the downstream merging firm.

Comparing equations (1) and (2), the vertical merger creates UPP on a foreclosed rival that is identical to the UPP that would be created if the rival were to acquire a silent ownership share equal to the cost pass-through rate of the upstream merging firm (i.e., $BRD = PTR_U$).²² Thus, this is the equivalent hypothetical partial ownership transaction.

For example, suppose that the cost pass-through rate is equal to 50%.²³ Then, for each foreclosed rival, the UPP is identical to that from a hypothetical acquisition by the rival of a 50% silent ownership share in the downstream merging firm. If there are multiple rivals that would be foreclosed with input price increases, then each of them would behave “as if” it had obtained a 50% silent ownership share in the downstream merging firm.²⁴ The effects of each of these hypothetical transactions involving the targeted downstream rivals would need to be summed up to evaluate the total competitive effect.²⁵

3. Contribution to the dHHI in the Downstream Market

This UPP analysis thus shows how the impact of potential input foreclosure on the pricing incentives of targeted downstream rivals can be recaptured by the downstream merging firm.

Applying the *mHHI* formula, the increase in effective concentration in the downstream market, as measured by the *mHHI*, is equal to 200 (i.e., $0.5 \times 20 \times 20$).

Example: Suppose instead that the upstream merging firm has two downstream customers that it fully supplies and targets both of them for input foreclosure. In this case, the increase in effective concentration is equal to 400 (i.e., $2 \times 0.5 \times 20 \times 20$).

This contribution to the *dHHI* arises from the impact of input foreclosure on the incentives of the foreclosed downstream rivals. We turn next to the analysis of the impact of the vertical merger on the incentives of the downstream merging firm.

B. Hypothetical Horizontal Transaction to Capture the UPP of the Downstream Merging Firm

A vertical merger also changes the incentives of the downstream merging firm. The vertical merger reduces the incentive of the downstream merging firm to compete against rivals that are customers of the upstream merging firm.²⁷ This is another way in which merging firms may be seen as indirect competitors in the pre-merger market. Suppose that the upstream merging firm is supplying inputs in the pre-merger market to some rivals of the downstream merging firm. For simplicity, assume further that the downstream merging firm is not a customer of the upstream merging firm.²⁸ By unilaterally raising its output price, the downstream merging firm will lose some sales, and a fraction of the lost sales will be captured by (i.e., diverted to) rival downstream firms, including those rivals that are customers of the upstream merging firm. It follows that the vertical merger would incentivize the downstream merging firm to raise its output price because doing so would increase the input sales made by the upstream merging firm to the downstream rivals. In the pre-merger market equilibrium, the downstream merging firm has no incentive to raise its output price to gain this effect. This is because the pre-merger downstream merging firm would have no reason to take into account any benefit received by the future upstream merger partner. Post-merger, however, the merged firm will have the incentive to internalize the benefit obtained by its upstream division when the downstream division raises its output price.

The vertical merger creates a type of indirect horizontal consolidation between the downstream merging firm and the rival firms that are customers of the upstream merging firm. As we discussed above, we proxy for this vertical merger effect by considering that the downstream merging firm has an *identical* incentive to raise price “as if” it had acquired a silent partial

²⁷ Chen, *supra* note 15.

²⁸ In this simple example, there cannot be any EDM since the downstream merging firm is not a customer of the upstream merging firm. Because we are focusing solely on a measure of effective concentration, we do not take into account any merger-specific EDM or other efficiencies at this stage of the analysis.

—

$$R) \frac{7}{2} \frac{2}{2} + L \frac{4}{2} \frac{5}{2} \frac{H}{1} \frac{9}{2} \frac{\hat{E}}{2} \quad (3)$$

where DR_{DR} denotes the diversion ratio from the downstream merging firm to a given rival, S_{UR} denotes the upstream merging firm's share of that rival's input purchases, W_{UR} and M_{UR} denote the upstream merging firm's price and percentage margin for input sales to that rival, and P_D denotes the downstream merger partner's output price.³² We consider the diversion to each rival separately and, therefore, the total effect is found by aggregating across all rivals.

As explained above, it is important to recognize that $vGUPPI$ measures only a first-round effect and fails to take account of a number of important feedback effects. The $vGUPPI$ specifically holds constant the input prices of the upstream merging firm at the pre-merger level, and thus holds constant both the upstream merging firm's dollar margin (i.e., $M_{UR} \times W_{UR}$ in equation (3)) and the upstream merging firm's share of the rival's input purchases (i.e., S_{UR} in equation (3)). Thus, $vGUPPI$ scores only the first-round incentive to raise the output price of the downstream merging firm *before* there are any increases in the input price charged to any foreclosed downstream rivals. Specifically, it does *not* take account of the impact of raising rivals' costs on the pricing incentives of the downstream merging firm.³³ Nor does it take account of the impact of raising rivals' costs on the pricing incentives of the competing upstream firms and of the competing downstream firms that are not foreclosed. In a full merger analysis, all those feedback effects would be taken into account.

2. The Equivalent Hypothetical Horizontal Transaction

The vertical merger creates UPP on the output price of the downstream merging firm. This creates a horizontal effect that is analogous to the effect that would occur if there were no vertical merger but the downstream merging firm instead were to behave "as if" it had acquired a silent partial ownership interest in each downstream rival that purchases inputs from the upstream merging firm. The effect of such hypothetical, horizontal partial acquisition on the downstream merging firm's pricing incentives is gauged by the horizontal $mGUPPI$. Formally,

explicitly in the formula (as it is accounted for in the calculation of the input "price" or input cost per unit of output).

³² This incentive to raise the price of the downstream merging firm can be explained as follows. If the downstream merging firm raises its price, a fraction of its lost sales (DR_{DR}) will be diverted to the downstream rival under consideration. However, that rival may use the upstream merging firm for a share (S_{UR}) of its input purchases, in which case the upstream merging firm gains incremental sales ($DR_{DR} \times S_{UR}$) and earns a dollar margin ($M_{UR} \times W_{UR}$) on each incremental sale. Normalizing this effect as a percentage of the output price of the downstream merging firm (P_D) yields equation (3).

³³ Similarly, the previous analysis of the pricing incentives of the upstream merging firm did not take account of the impact of raising the output price of the downstream merging firm.

$$1) 7 2 2 + @ \$_{1/2} \ddot{E} H \& 4_{1/2} \ddot{E} H \ddot{E} / H \frac{2\ddot{E}}{2_{1/2}} \quad (4)$$

where B_{DR} denotes the hypothetical, silent ownership share obtained by the downstream merging firm in the rival under consideration, and M_R denotes that rival's percentage margin. Note that the factor $DR_{DR} \times M_R \times P_R / P_D$ in equation (4) is the standard horizontal GUPPI of the downstream merging firm for a hypothetical merger with that rival.

Comparing equations (3) and (4), it follows that the vertical merger creates UPP on the downstream merging firm that is identical to the UPP that would be created if the downstream merging firm instead were to acquire a silent ownership share in that rival equal to:³⁴

$$B_{DR} = \frac{M_{UR} \times W_{UR} \times S_{UR}}{M_R \times P_R} \quad (5)$$

In words, this equivalent ownership share is equal to the upstream merging firm's share of the downstream rival's input purchases (S_{UR}) multiplied by the upstream merging firm's dollar margin on input sales made to that rival ($M_{UR} \times W_{UR}$) and divided by the rival's dollar margin ($M_R \times P_R$).

For example, suppose that the ratio of the upstream to downstream dollar margins is 0.3, and consider a downstream rival that purchases exclusively from the upstream merging firm, that is, $S_{UR} = 100\%$. Then, diversion to that rival creates UPP on the downstream merging firm that is identical to that from a hypothetical acquisition by the downstream merging firm of a 30% (i.e., $100\% \times 0.30$) silent financial ownership share in that rival. If there are multiple rivals that are customers of the upstream merging firm, then there are additional effects that must similarly be taken into account and added together to obtain the total effect on the $mHHI$.

The effect of the vertical merger on the downstream merging firm's pricing incentives (ignoring EDM) thus is the same as the effect on incentives from a horizontal partial ownership acquisition by the downstream merging firm of each foreclosed downstream rival, where the partial interest is a share B_{DR} that account for the upstream merging firm's share of the downstream rival's input purchases and the fact that the upstream merging firm's dollar margin is typically only a fraction of the downstream rival's dollar margin.

3. Contribution to the dHHI in the Downstream Market

This analysis thus shows how the impact of UPP on the downstream merging firm (created by the vertical merger) can be reckoned into a $dHHI$ calculation. The $dHHI$ contribution of the

³⁴ Equation (5) is obtained by setting (3) equal to (4) and solving for B_{DR} .

*vGUPPI*d can be measured by the increase in the *mHHI* of the equivalent hypothetical partial ownership transactions. The following examples show how this is calculated.

Example: Consider again the previous example with five symmetric downstream firms that each have 20% market share. Suppose that the upstream merging firm supplies 100% of the input needs of a single downstream rival and that this one downstream rival is the only customer of the merged firm. Suppose that the dollar margin ratio (of the upstream merging firm to that rival) is 0.3. In this example, the increase in effective concentration in the downstream market, as measured by the *mHHI*, is equal to 120 (i.e., $0.3 \times 20 \times 20$).

Example: Suppose instead that the upstream merging firm supplies 100% of the input needs of two downstream rivals and these downstream rivals are the only two customers of the merged firm, and the dollar margin ratio is 0.3. The increase in effective concentration now is equal to 240 (i.e., $2 \times 0.3 \times 20 \times 20$).³⁵

The increases in the *mHHI* for these examples reflect only the UPP on the downstream merging firm's output price. The *dHHI* measure must account for that UPP as well as the UPP on the foreclosed rivals' prices, as discussed next. Before doing so, it is useful to repeat that the incentive of the downstream merging firm to raise price in order to drive additional sales to the upstream merging firm occurs even if there is no foreclosure concern. This can lead to a large *dHHI* even if there are no foreclosure concerns, which could be relevant to enforcement if merger-specific EDM is small or non-existent.³⁶

C. The dHHI

The previous sections described two types of hypothetical horizontal transactions that *together* can be used to proxy for a vertical merger that raises input foreclosure concerns, and hence evaluate the merger's impact on effective concentration in the downstream market. These two hypothetical transactions involve several partial ownership interests among the downstream

³⁵ If instead there are two downstream customers but each one purchases only 50% of its input purchases from the upstream merging firm, then the increase in effective concentration is equal to 120 (that is, $2 \times 0.5 \times 0.3 \times 20 \times 20$).

³⁶ If there are no foreclosure concerns and the downstream firms are not symmetric, then the UPP may outweigh the EDM of the downstream merging firm when the pre-merger $\Delta E I$ to $M H Q p^\circ$) $\bullet 0 p \tilde{n}V3 U W L 0 p \in$

firms, which then can be combined in order to evaluate their total impact on the effective level of concentration in the downstream market. The $dHHI$ measures that total impact.

The $dHHI$ specifically is equal to the sum of the individual $dHHI$ s from each of these proxy transactions, that is, (i) each of the foreclosed rivals acquiring a silent financial interest $B_{RD} = PTR_U$ in the downstream merging firm, and (ii) the downstream merging firm acquiring a silent financial interest $B_{DR} = S_{UR} \times M_{UR} \times W_{UR} / (M_R \times P_R)$ in each rival that purchases the input of the upstream merging firm. Applying this formula to the two types of hypothetical transactions, we obtain the total increase in the $dHHI$,

$$\Delta dHHI = \sum_R S_{UR} \times \frac{M_{UR} \times W_{UR}}{M_R \times P_R} \times S_R \times S_D \quad (6)$$

where S_D denotes the market share of the downstream merging firm, S_F denotes the total market share of foreclosed rivals in the downstream market, and S_R is the market share of an individual rival of the downstream merging firm. Note that the last term in equation (6) is a summation over all the rivals of the downstream merging firm.

Consider again the case where all the rivals of the downstream merging firm are similarly situated in that they all procure the same share α of their input needs from the upstream merging firm, and they all have the same margin ratio $M_{UR} \times W_{UR} / (M_R \times P_R)$. If they all are potential targets for input foreclosure, then the above $dHHI$ becomes

$$\Delta dHHI = \alpha \times \sum_R \frac{M_{UR} \times W_{UR}}{M_R \times P_R} \times S_R \times S_D \quad (7)$$

This expression can be used to measure the increase in effective concentration in the downstream market that results from a vertical merger that raises input foreclosure concerns.

The $dHHI$ calculation can be illustrated by combining the two parts of the previous numerical examples, where we assume $PTR_U = 50\%$, $M_{UR} \times W_{UR} / (M_R \times P_R) = 0.3$, and $S_D = 20\%$.

Example: Suppose only one downstream rival is customer of the upstream merging firm and purchases the input exclusively from the upstream merging firm (that is, $\alpha = 1$), and this customer is targeted for input foreclosure. Thus, $dHHI = (0.5 + 0.3) \times 20 \times 20 = 320$. This is the sum of the $dHHI$ contribution of 200 from the transaction equivalent to the $vGUPPI_r$ and a contribution of 120 from the transaction equivalent to the $vGUPPI_d$.

Example: Suppose instead that two downstream rivals are fully supplied by the upstream merging firm and are potentially targeted for input foreclosure. In this case, the $dHHI$ is 640, which is comprised of a contribution of 400

from the transaction equivalent to the $vGUPPI_r$ and 240 from the transaction equivalent to the $vGUPPI_d$.

These examples indicate the need to identify the set of downstream rivals that might be targeted for input foreclosure by the merged firm. All the rivals must be identified in order to obtain an accurate $dHHI$ measure.

IV. Applying the $dHHI$ in Vertical Merger Analysis

The $dHHI$ and the associated *post-merger HHI* levels have several possible roles in vertical merger analysis. They can be used as a rough gauge of competitive concerns in vertical mergers involving potential input foreclosure. They also in principle might be useful in forming a safe harbor screen or a concentration-based anticompetitive presumption for vertical mergers that raise input foreclosure concerns, possibly along with other evidence.

A. The Role of the $dHHI$

The $dHHI$ can be used as an initial, rough gauge of the competitive concerns from a vertical merger that involves potential input foreclosure. The $dHHI$ only measures first-round effects on pricing incentives, just as do the standard GUPPIs used in horizontal merger analysis. Focusing on these first-round effects, a higher $dHHI$ suggests greater anticompetitive concerns.

These first-round effects on pricing incentives specifically exclude the following feedback effects.

First, the first-round effects do not take into account the impact of the pricing incentives of the targeted rivals (following input foreclosure) on the pricing incentives of the downstream merging firm. Nor do they take into account the impact of the pricing incentives of the downstream merging firm on the pricing incentives of the targeted rivals. These feedback effects could exacerbate the competitive harms, just as is the case for horizontal mergers. In Section V, we show how simultaneous effects on pricing incentives can be calculated, just as they can for horizontal GUPPIs.³⁷

Second, the first-round effects assume that non-targeted downstream firms do not change their prices in response to the foreclosure of the targeted downstream rivals. Since the foreclosed rivals will have the incentive to raise their prices, these non-targeted competitors would tend to have the incentive to respond by raising their prices. This also creates feedback effects among

³⁷ The simultaneous GUPPIs for horizontal mergers are equal to the compensating marginal cost reductions (“CMCRs”) expressed as a percentage of price. Gregory J. Werden, *A Robust Test for Consumer Welfare Enhancing Mergers Among Sellers of Differentiated Products*, 44 J. INDUS. ECON. 409 (1996). The corresponding price increases at \$ G M 5

the price increases that could exacerbate the competitive harms further, just as it occurs for horizontal mergers.

Third, the first-round effects do not take into account possible entry or repositioning by competing upstream firms or non-targeted downstream firms. Nor do they take into account possible repositioning by the upstream and downstream divisions

occur. If instead the upstream rivals would not fully match, then there would be some input substitution and that would tend to reduce the $dHHI$ depending on the elasticity of substitution and the extent of partial price matching. The $dHHI$ that we have proposed (assuming no input substitution and no responses by upstream rivals) likely is a good approximation for the case with both input substitution and responses from upstream rivals. While one cannot claim that there would be full price matching by upstream rivals and hence no input substitution, that assumption is the conservative one.⁴² The assumption of full matching also might suggest a conservative approach to any anticompetitive presumption based solely on the $dHHI$ (and associated *post-merger HHI*).

V. The vGUPPI Methodology, Feedback Effects, and Simultaneous vGUPPIs

Preliminary analysis of vertical mergers involving input foreclosure concerns might focus directly on the vGUPPIs themselves rather than using the partial ownership $dHHI$ proxy that is based on the vGUPPIs. If there is no input substitution, these vGUPPIs are relatively simple to calculate, as shown above in equations (1) and (3).

Two recent working papers have suggested that the vGUPPI methodology is not useful because the $vGUPPI_u$ always predicts that the merged firm will have an incentive to raise rivals' costs, but a simulation model that takes into account the existence of merger-specific EDM may predict that the merged firm actually will decrease the input price that it charges to downstream rivals.⁴³ These papers also have suggested that $vGUPPI_r$ is similarly a poor proxy for the downstream effects in the presence of merger-specific EDM, because $vGUPPI_r$ always predicts that the foreclosed rivals will have an incentive to raise price, when there are in fact situations where a simulation model predicts that rivals will be foreclosed and yet will reduce prices to consumers.

A. Explaining the Feedback Effects

We did not intend to give the impression that each of the simple vGUPPIs derived in our article should be examined in a vacuum when there is merger-specific EDM. We reported several $vGUPPI_d$ measures: $vGUPPI_d1$ does not take EDM into account because merger-specific EDM may not occur; $vGUPPI_d2$ takes merger-specific EDM into account and may be negative; and $vGUPPI_d3$ takes EDM into account and assumes further efficiencies from input substitution.⁴⁴

⁴² In addition, all the potentially foreclosed firms should be included in the analysis.

⁴³ Gopal Das Varma & Martino De Stefano, *Equilibrium Analysis of Vertical Mergers*

Merger-specific EDM can mitigate the UPP or even offset it. To account for these feedback effects, we suggested that a full simulation model could be estimated and run.⁴⁵ The two working papers discussed here took the simulation approach and compared their results with the simple $vGUPPI$ s when there is significant merger-specific EDM.

The situations where $vGUPPI_u$ and $vGUPPI_r$ do not perform well in the simulation models (in the sense that they have the wrong sign) can be explained and accounted for in a very simple way.

First, those studies consider situations where EDM is relatively large. When merger-specific EDM is relatively small, $vGUPPI_u$ and $vGUPPI_r$ perform well. In fact, in the absence of any merger-specific EDM, the $vGUPPI_d$ is positive. In this situation, the $vGUPPI_d$ reinforces the upward pricing pressure from the $vGUPPI_r$ or $vGUPPI_u$.

Second, the price reductions found in the two working papers are not om

B. Simultaneous vGUPPIs

We turn next to the derivation of these simultaneous vGUPPIs. Consider the model used in two working papers: a monopolist upstream supplier (U) sells inputs to two downstream

manufacturers (D1 and D2). The upstream supplier has a constant marginal cost c and a constant marginal cost of providing information λ . The downstream manufacturers have constant marginal costs c_1 and c_2 and constant marginal costs of providing information λ_1 and λ_2 . The upstream supplier's profit is $\pi_U = (p_U - c)Q$ and the downstream manufacturers' profits are $\pi_{D1} = (p_{D1} - c_1)Q_1$ and $\pi_{D2} = (p_{D2} - c_2)Q_2$. The upstream supplier's profit function is $\pi_U = (p_U - c)Q$ and the downstream manufacturers' profit functions are $\pi_{D1} = (p_{D1} - c_1)Q_1$ and $\pi_{D2} = (p_{D2} - c_2)Q_2$.

simulation model for the non-monopoly scenario with input substitution, and where the upstream competitors have the incentive to accommodate post-merger changes in the input price charged by the merged firm, the overall results also could differ substantially. A model of a monopoly supplier is not the best model to guide vertical merger policy.

VI. Conclusions

The *dHHI* shows that vertical mergers involving input foreclosure concerns have an analogue to horizontal consolidation in the downstream market. This is a significant result because it shows that there is not the type of inherent difference in the effects of vertical and horizontal mergers that is sometimes claimed. At the same time, we do not want to overclaim that the use of the *dHHI* and the resulting *post-merger HHI* is an airtight gauge of the likely impact of vertical mergers that raise input foreclosure concerns. As we have stressed in this comment, the *dHHI* gauges only first-round effects and only for unilateral input foreclosure. The same point applies to analysis directly based on the levels of the vGUPPIs. However, we are confident that using the *HHI* either alone or in conjunction with our *dHHI* approach would provide a better gauge than the 20% safe harbor market share threshold in the draft VMGs.⁵⁵ Therefore, we believe that the *dHHI* approach should be investigated further.

⁵⁵ Draft VMGs, *supra* note 3, at 3.
